Message Passing Decoder with Decoding on Zigzag Cycles for Non-binary LDPC Codes*

Takayuki NOZAKI[a], Kenta KASAI[b], Members, and Kohichi SAKANIWA[c], Fellow

SUMMARY In this paper, we propose a message passing decoding algorithm which lowers decoding error rates in the error floor regions for non-binary low-density parity-check (LDPC) codes transmitted over the binary erasure channel (BEC) and the memoryless binary-input output-symmetric (MBIOS) channels. In the case for the BEC, this decoding algorithm is a combination with belief propagation (BP) decoding and maximum a posteriori (MAP) decoding on zigzag cycles, which cause decoding errors in the error floor region. We show that MAP decoding on the zigzag cycles is realized by means of a message passing algorithm. Moreover, we extend this decoding algorithm to the MBIOS channels. Simulation results demonstrate that the decoding error rates in the error floor regions by the proposed decoding algorithm are lower than those by the BP decoder.

key words: non-binary LDPC code, error floor, memoryless binary-input output-symmetric, belief propagation decoder, maximum a posteriori decoding

1. Introduction

Gallager invented low-density parity-check (LDPC) codes [1]. Due to the sparseness of the parity check matrices, LDPC codes are efficiently decoded by the belief propagation (BP) decoder. Optimized LDPC codes can exhibit performance very close to the Shannon limit [2]. Davey and MacKay [3] have found that non-binary LDPC codes can outperform binary ones. In this paper, we assume the non-binary LDPC codes defined over $F_{2^m}$ transmitted over the memoryless binary-input output-symmetric (MBIOS) channels, where $F_{2^m}$ is the finite field of order $2^m$.

A non-binary LDPC code over $F_{2^m}$ is defined by the null space of a sparse parity-check matrix over $F_{2^m}$. A Tanner graph for a non-binary LDPC code is represented by a bipartite graph with variable nodes, check nodes and labeled edges. Each LDPC code is represented by Tanner graphs. It is known that Tanner graphs of optimized irregular non-binary LDPC codes contain variable nodes of degree two [4].

The curve of the decoding error rate for a finite code length LDPC code is divided into two regions called waterfall region and error floor region, or simply waterfall and error floor. In the waterfall, the decoding error rate drops off steeply as the function of channel error probability. The waterfall is mainly caused by the large weight errors. In the error floor, the decoding error rate has a gentle slope. The error floor is mainly caused by the small weight errors. In this paper, we investigate the decoding error rates in the error floors for non-binary LDPC codes.

A zigzag cycle is a simple cycle, or a circuit such that variable nodes are of degree two in the Tanner graph. Since the zigzag cycles cause small weight errors, the decoding error rates in the error floors are mainly caused by zigzag cycles. Hence, in this paper, we focus on the decoding errors in the zigzag cycles to lower the decoding error rates in the error floors.

There are two approaches to lowering the decoding error rates in the error floors: by optimizing the code and by improving the decoder. By optimizing labels in the zigzag cycles in non-binary LDPC codes, the decoding error rates in the error floors were lowered by [5], [6]. On the other hand, there are no message passing (MP) decoders lowering the decoding error rates in the error floors.

In this paper, we propose an MP decoding algorithm reducing the decoding errors in the zigzag cycles. Firstly, we investigate the maximum a posteriori (MAP) decoding algorithm for the non-binary LDPC codes over the binary erasure channels (BECs). From this result, we show that MAP decoding on the zigzag cycles is realized by means of an MP algorithm for the BEC. Secondly, we propose an MP decoding algorithm by combining with BP decoding and decoding on the zigzag cycles for the non-binary LDPC codes over the BECs. Thirdly, we extend the proposed MP decoding algorithm to the MBIOS channels. Finally, we show by simulation results that the decoding error rates in the error floors by the proposed decoding algorithm are lower than those by the BP decoder.

The remainder of this paper is organized as follows: Sect. 2 defines non-binary LDPC codes and introduces BP and MAP decoding algorithms for the non-binary LDPC codes. Section 3 reviews a MAP decoding algorithm on the zigzag cycles over the BEC. Section 4 proposes a decoding algorithm which reduces the decoding erasure rates in the error floors for non-binary LDPC codes over the BEC. Section 5 extends the algorithm proposed in Sect. 4 to the MBIOS channels. Simulation results in Sect. 6 demonstrate that the proposed decoding algorithm lowers the decoding error rates in the error floors.
2. Preliminaries

This section defines non-binary LDPC codes and introduces channel models. Moreover, we recall BP and MAP decoding algorithms for the non-binary LDPC codes over the MBIOS channel and the BEC, respectively. This section introduces some notations throughout used in this paper.

2.1 Non-binary LDPC Codes

A non-binary LDPC code over \( \mathbb{F}_{2^m} \) is defined by the null space of a sparse parity-check matrix \( H = (h_{i,j}) \in \mathbb{F}_{2^m}^{M \times N} \):

\[
\{ x \in \mathbb{F}_{2^m}^N \mid Hx^T = 0^T \in \mathbb{F}_{2^m}^M \}.
\]

Note that \( N \) is called symbol code length.

In this paper, we consider a non-binary LDPC code represented by a Tanner graph \((V \cup C, E)\), where \( V = \{v_1, v_2, \ldots, v_N\} \), \( C = \{c_1, c_2, \ldots, c_M\} \) and \( E \) are the sets of the variable nodes, the check nodes and the labeled edges, respectively. The \( v \)-th variable node and the \( c \)-th check node are connecting to an edge labeled as \( h_{v,c} \in \mathbb{F}_{2^m} \) \( \setminus \{0\} \) if \( h_{v,c} \neq 0 \).

The LDPC codes defined by Tanner graphs with the variable nodes of degree \( d_v \) and the check nodes of degree \( d_c \) are called \((d_v, d_c)\)-regular LDPC codes. Each irreducible LDPC code is characterized by a pair of degree distributions \( \Lambda(x) = \sum_{i} \Lambda_i x^i \) and \( P(x) = \sum_{i} P_i x^i \), where \( \Lambda_i \) (resp. \( P_i \)) represents the number of the variable nodes (resp. check nodes) of degree \( i \). Notice that \( N = \sum \Lambda_i \) and \( M = \sum P_i \). It is known that optimized irregular non-binary LDPC codes contain variable nodes of degree two [4]. In particular, \((2,d_c)\)-regular non-binary LDPC codes exhibit good decoding performance among other LDPC codes for \( 2^m \geq 64 \).

2.2 Channel Model

Let \( v \) be a primitive element of \( \mathbb{F}_{2^m} \). Once a primitive element \( v \) of \( \mathbb{F}_{2^m} \) is fixed, each symbol is given by an \( m \)-bit representation [7, p.110]. We denote the \( m \)-bit representation of \( y \in \mathbb{F}_{2^m} \), by \( b(y) = (b_1(y), b_2(y), \ldots, b_m(y)) \).

For integers \( a, b \), we denote the set of integers between \( a \) and \( b \), as \( [a; b] \). Note that \( [a; b] = \emptyset \) if \( a > b \). By using the \( m \)-bit representation, we regard each codeword \( \mathbf{x} = (x_1, x_2, \ldots, x_N) \) in a non-binary LDPC code as a binary codeword, i.e., a codeword is represented by \( (x_{11}, x_{12}, \ldots, x_{1m}) \), \( (x_{21}, x_{22}, \ldots, x_{2m}) \), \ldots, \( (x_{N1}, x_{N2}, \ldots, x_{Nm}) \), where \( x_{i,j} = b_j(x_i) \) for \( i \in [1; N] \) and \( j \in [1; m] \). Hence, the codewords in the non-binary LDPC codes defined over \( \mathbb{F}_{2^m} \) are able to be transmitted over binary channels. We denote the received word as \( \mathbf{y} = (y_1, y_{12}, \ldots, y_{NM}) \).

A binary input channel is called memoryless if

\[
p(y \mid x) = \prod_{i=1}^{N} \prod_{j=1}^{m} p(y_{i,j} \mid x_{i,j}).
\]

We transform the binary input alphabets \{0, 1\} into \{+1, −1\}. With some abuse of notation, we make no distinction between \{0, 1\} and \{+1, −1\}. A memoryless binary-input channel is called output-symmetric if

\[
p(y \mid x) = p(-y \mid -x).
\]

We assume the transmission over the MBIOS channel. Examples of the MBIOS channels include the BEC and the binary additive white Gaussian noise (BAWGN) channel.

2.3 BP Decoding Algorithm for MBIOS Channel

In the BP decoding algorithm, each edge in a Tanner graph transfers a message. The messages arising in the BP decoder for non-binary LDPC codes over \( \mathbb{F}_{2^m} \) are vectors of length \( 2^m \). Let \( \Phi^{(t)}_{c,v} \) (resp. \( \Phi^{(t)}_{v,c} \)) be the message from the \( v \)-th variable node (resp. \( c \)-th check node) to the \( c \)-th check node (resp. \( v \)-th variable node) at the \( t \)-th iteration.

(1) Initialization

Set \( t = 0 \). Recall that \( N \) and \( M \) represents the number of variable nodes and check nodes in the Tanner graph, respectively. For \( v \in [1; N] \), let \( C_v = (C_v(0), C_v(1), \ldots, C_v(\alpha^{2^m}-2)) \) denote the initial message of the \( v \)-th variable node. For \( y \in \mathbb{F}_{2^m} \), the component \( C_v(y) \) of the initial message is derived from the channel outputs as follows:

\[
C_v(y) = \prod_{i=1}^{m} \Pr(Y_{v,i} = y_{v,i} \mid X_{v,i} = b_i(y)).
\]

Let \( N_v(i) \) (resp. \( N_c(j) \)) be the set of indices of the check nodes (resp. variable nodes) adjacent to the \( i \)-th variable node (resp. the \( j \)-th check node). Set for all \( c \in [1; M] \) and \( v \in N_c(c) \),

\[
\Phi^{(0)}_{c,v} = (2^{-m}, 2^{-m}, \ldots, 2^{-m}).
\]

(2) Iteration and Decision

The convolution of two vectors \( \Psi_1 \) and \( \Psi_2 \) is defined as

\[
[\Psi_1 \oplus \Psi_2](x) := \sum_{y \in \mathbb{F}_{2^m}} \Psi_1(y) \Psi_2(x - y).
\]

To simplify the notation, we define \( \bigoplus_{i \in [1; \delta]} \Psi_i := \Psi_1 \oplus \Psi_2 \oplus \cdots \oplus \Psi_\delta \). Define

\[
\arg\max_{x \in \mathbb{F}_{2^m}} \Psi(x) := \{ x \in \mathbb{F}_{2^m} \mid \Psi(x) \geq \Psi(y) \forall y \in \mathbb{F}_{2^m} \}.
\]

The BP decoding algorithm is described as follows:

1. In the \( v \)-th variable node, the message \( \Phi^{(t)}_{v,c} \) is given by

\[
\Psi^{(t)}_{v,c}(x) = \xi^{-1} C_v(x) \prod_{c' \in N_v(c)} \Phi^{(t)}_{c',v}(x),
\]

for \( x \in \mathbb{F}_{2^m} \), where \( \xi \) is a normalization factor such that

\[
1 = \sum_{x \in \mathbb{F}_{2^m}} \Psi^{(t)}_{v,c}(x).
\]

2. In the \( c \)-th check node, the message \( \Phi^{(t+1)}_{c,v} \) is calculated as,

\[
\Phi^{(t+1)}_{c,v}(x) = \Psi^{(t+1)}_{c,v}(h_{c,v}^{-1} x), \quad \Phi^{(t+1)}_{c,v} = \bigoplus_{v' \in N(c)} \Phi^{(t+1)}_{c,v'}(x),
\]

\[
\Phi^{(t+1)}_{c,v}(x) = \Phi^{(t+1)}_{c,v}(h_{c,v}^{-1} x).
\]

3. In the \( v \)-th variable node, the decoding result \( D_v^{(t)} \subseteq \mathbb{F}_{2^m} \) is calculated from

\[
D_v^{(t)} = \arg\max_{x \in \mathbb{F}_{2^m}} C_v(x) \prod_{c \in N_v(c)} \Phi^{(t)}_{c,v}(x).
\]
In this paper, we consider the known that the set of variable nodes with decoding erasures using the decoding rule \( y \) is set as the unique element of \( D \). Otherwise, set \( x_v =? \), the \( v \)-th symbol is correctly decoded, where \( x_v \) is the \( v \)-th transmitted symbol. Otherwise, the \( v \)-th variable node has a decoding error.

2.4 BP Decoding Result for BEC

In this section, we review the BP decoding algorithm for the non-binary LDPC codes over the BECs. In the case for the BEC, the messages arising in the BP decoder satisfy a property such that all the non-zero entries in a message are equal [8, Lemma 2]. Hence, the \( v \)-th symbol is correctly decoded if and only if \( |D_v| = 1 \).

We denote the set of the indices of the variable nodes with decoding erasures, by \( D \), namely, \( D := \{ i \in [1;N] | |D_i| > 1 \} \). Define \( \bar{D} := [1;N] \setminus D \). In words, \( \bar{D} \) represents the set of indices of the variable nodes which are correctly decoded. For \( j \in [1;M] \), we define the syndrome \( s_j \) for the \( j \)-th check node as

\[
s_j = \sum_{i \in D_j} h_{j,i} x_i \in \mathbb{F}_{2^m}.
\]

Notice that the empty sum \( \sum_{i \in \emptyset} a_i \) is equal to zero for any \( a_1, \ldots, a_k \in \mathbb{F} \).

We refer to the subgraph constructed by the variable nodes with decoding erasures as the residual graph [9] after BP decoding. More precisely, a residual graph \( (V_D \cup \mathcal{C}_D, E_D) \) is a subgraph of the Tanner graph such that \( V_D = \{ i | |D_i| \neq 1 \} \), \( E_D \) is the set of all the edges connecting to \( V_D \) and \( \mathcal{C}_D = \{ c_j | \exists \beta_j \in V_D \text{ s.t. } j \in N_c(i) \} \).

A stopping set \( S \) is a set of variable nodes such that all the neighbors of \( S \) are adjacent to \( S \) at least twice. It is known that the set of variable nodes with decoding erasures forms a stopping set.

2.5 MAP Decoding Algorithm for BEC

In this paper, we consider the symbol-wise MAP decoding using the decoding rule

\[
D_{i}^{\text{MAP}}(y) = \arg \max_{y \in \mathbb{F}_{2^m}} p_{X_i}(y | y),
\]

for a given received word \( y \in Y = Y^{Nv} \). In the case for the BEC, the received word \( y \) fulfills \( y_{i,j} = x_{i,j} \) if the bit \( y_{i,j} \) is received correctly. We assume that codewords are chosen uniformly. Define

\[
X_{\text{MAP}}(y) = \{ x \in C | H x^T = 0^T, x_{i,j} = y_{i,j} \}
\]

for \( (i, j) \in [1;N] \times [1;m] \) s.t. \( y_{i,j} \in \{ 0, 1 \} \).

The symbol-wise MAP decoding for the \( i \)-th symbol is given by the set of the \( i \)-th symbol in \( X_{\text{MAP}}(y) \), i.e.,

\[
D_{i}^{\text{MAP}}(y) = \{ x_i \in \mathbb{F}_{2^m} | x \in X_{\text{MAP}}(y) \}.
\]

The \( i \)-th symbol is correctly decoded if and only if \( |D_{i}^{\text{MAP}}(y)\| = 1 \). Let \( \hat{s}_i^{\text{MAP}} \) be the \( i \)-th output of the MAP decoding algorithm. If \( |D_{i}^{\text{MAP}}(y)\| = 1 \), \( \hat{s}_i^{\text{MAP}} \) is set the unique element of \( D_{i}^{\text{MAP}}(y) \). Otherwise, set \( \hat{s}_i^{\text{MAP}} =? \).

It is well known that if symbols are decoded under BP decoding, the symbols also are decoded under MAP decoding. Hence, \( X_{\text{MAP}} \) is rewritten as

\[
X_{\text{MAP}} = \{ x \in C | H x^T = 0^T, x_{i} \in D_i \text{ for } i \in [1;N]\}
\]

where \( H_D \) denotes the submatrix of \( H \), restricted to the columns indexed by \( D \), \( x_D \) denotes the corresponding sub-vector of \( x \) and \( s = (s_1, s_2, \ldots, s_m) \). Thus, the \( i \)-th symbol is correctly decoded under symbol-wise MAP decoding if \( H_D x_D^T = 0^T \) has a unique solution.

3. MAP Decoding on Zigzag Cycles over BEC

In this section, we define the zigzag cycles in the non-binary LDPC codes and we show MAP decoding results for the zigzag cycles over the BEC.

3.1 Zigzag Cycle

**Definition 1:** A zigzag cycle is a simple cycle or a circuit such that all the variable nodes in the zigzag cycle are of degree two. More precisely, a zigzag cycle \( (V_{zc} \cup C_{zc}, E_{zc}) \) is a connected subgraph [10] of the Tanner graph such that all the variable nodes in \( V_{zc} \) are of degree two, \( E_{zc} \) is the set of all the edges connecting to the variable nodes in \( V_{zc} \) and the check nodes in \( C_{zc} \) connect to the edges in \( E_{zc} \) at exactly twice.

Since the zigzag cycles cause small weight errors, the decoding error rates in the error floors are mainly caused by zigzag cycles. All the zigzag cycles cause decoding erasures under BP decoding for the BEC if all the bits in the zigzag cycles are received erasures, i.e., \( \forall i \in V_{zc}, \forall j \in [1;m] \) \( y_{i,j} =? \) [11, Appendix A.2]. However, most of the zigzag cycles are decodable under MAP decoding even if all the bits in the zigzag cycles are received erasures. In the next section, we consider the zigzag cycles under MAP decoding.

3.2 MAP Decoding on Zigzag Cycles

In this section, we assume that the residual graph after BP decoding forms a zigzag cycle. To simplify the notation, we consider the zigzag cycle in the residual graph as in Fig. 1. In words, we consider a zigzag cycle of weight \( w \) labeled with \( h_{1,1}, h_{1,2}, h_{2,2}, \ldots, h_{w,w}, h_{w+1} \).

The submatrix \( H_{zc} \) corresponding to the zigzag cycle is

\[
H_{zc} = \begin{pmatrix}
h_{1,1} & h_{1,2} & 0 & \cdots & 0 \\
0 & h_{2,2} & h_{3,3} & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
h_{w,1} & 0 & 0 & \cdots & h_{w,w}
\end{pmatrix}
\]
To simplify the notation, we define for \( i \in [1; w] \), \( n \in \mathbb{Z} \)
\[
\begin{align*}
    h_{n+i} &:= h_{i,n+i}, \\
    \xi_i &:= h_{i-1} A_i^{-1}, \\
    \beta &:= \prod_{j=0}^{w} \xi_i.
\end{align*}
\]
Note that an empty product is equal to 1, i.e., \( \prod_{\emptyset} a_i = 1 \) for any \( a_1, a_2, \ldots, a_n \in \mathbb{N} \). To simplify the notation, we denote \( \chi^\text{MAP}_i \) as \( \hat{x}_i \) in this section. Recall that \( s_i \) represents the syndrome corresponding to the \( i \)-th check node. For a given \( s_1, s_2, \ldots, s_w \), the MAP decoding result \( (\hat{x}_1, \hat{x}_2, \ldots, \hat{x}_w) \) fulfills the following equation
\[
(\begin{array}{c} s_1 \\ s_2 \\ \vdots \\ s_w \end{array}) = H_{nc} (\begin{array}{c} \hat{x}_1 \\ \hat{x}_2 \\ \vdots \\ \hat{x}_w \end{array})^T.
\]
If the matrix \( H_{nc} \) is non-singular, i.e., \( \beta \neq 1 \), then the \( (i, j) \)-th entry of \( H_{nc}^{-1} \) is given as
\[
(H_{nc}^{-1})_{ij} = \begin{cases} 
(1 + \beta)^{-1} h_{i,j}^{-1} \prod_{k\in\{j+1:j\}} \xi_k, & i = j, \\
(1 + \beta)^{-1} h_{i,j}^{-1} \prod_{k\in\{i+1:i\}} \xi_k, & i > j.
\end{cases}
\]
From Eq. (2), the MAP decoding result \( \hat{x}_i \) is written as
\[
\hat{x}_i = \sum_{j=1}^{w} (H_{nc}^{-1})_{ij} s_j = A_{w,i}(1 + \beta)^{-1},
\]
for \( i \in [1; w] \), where
\[
A_{w,i} := h_{i,1}^{-1} \sum_{j=1}^{w} s_j \prod_{k\in\{j+1:j\}} \xi_{i+k}.
\]
In the case for \( A_{w,i} = 0 \) and \( \beta \neq 1 \), we obtain from (3)
\[
\hat{x}_i = 0.
\]
Define
\[
B_{w,i} := \beta^{-1} A_{w,i} = h_{i,1}^{-1} \sum_{j=1}^{w} s_j \prod_{k\in\{j+1:j\}} \xi_{i+k}.
\]
Then, the submatrix \( H_{nc} \) is non-singular if and only if
\[
\beta = A_{w,i} \neq 0 \Longleftrightarrow B_{w,i} \neq 0.
\]
for \( A_{w,i} \neq 0 \). For \( A_{w,i} = 0 \), the substitution \( \beta = A_{w,i} B_{w,i}^{-1} \) into Eq. (3) yields
\[
\hat{x}_i = A_{w,i} B_{w,i}(A_{w,i} + B_{w,i})^{-1}.
\]
Hence, if \( A_{w,i} \neq 0 \) and \( B_{w,i} \) are derived by an MP algorithm, we obtain the MAP decoding results on the zigzag cycles.

Now, we consider two recurrence relations
\[
a^{(0)}_{w,i} = h_{i-1}(h_{i-1} a^{(0)}_{w,i} + s_{i-1}),
\]
\[
a^{(2)}_{w,i} = h_{i-1}^{-1}(h_{i-1} a^{(2)}_{w,i} + s_{i-1}).
\]
Figure 1

A zigzag cycle of weight \( w \).

**Example 1:** Consider a zigzag cycle of weight 2 with labels \( h_{1,1}, h_{2,1}, h_{2,2}, h_{1,2} \). Figures 2 and 3 illustrate calculation of \( A_{2,1} \) and \( B_{2,1} \) in the Tanner graph, respectively. The second check node \( c_2 \) in Fig. 2 carries out the following calculations:

1. Multiply the incoming message by the label of the edge which transfers the incoming message to the check node.
2. Add the syndrome of the check node and the computation result of Step 1.
3. Multiply the computed result of Step 2 by the inverse of the label which transfers the outgoing message from the check node.

Section 4.2 realizes this calculation by an MP algorithm for any zigzag cycles with decoding erasures.

Section 4.2 realizes this calculation by an MP algorithm for any zigzag cycles with decoding erasures.
4. MP Decoder with Decoding on Zigzag Cycles for BEC

In this section, we propose an MP decoding algorithm which reduces the decoding erasure rates in the error floors for non-binary LDPC codes over the BEC. If there are variable nodes with erasures after BP decoding, the proposed decoding algorithm decodes the erasures in the zigzag cycles by MAP decoding algorithm. Hence, the proposed decoder needs to search the zigzag cycles with BP decoding erasures before MAP decoding on the zigzag cycles. Thus, the proposed decoding algorithm is divided into 3 steps: (i) BP decoding, (ii) zigzag cycle detection and (iii) MAP decoding on zigzag cycles. All the steps are realized by means of an MP algorithm. Steps (i), (ii) and (iii) are given in Sects. 2.3, 4.1 and 4.2, respectively.

4.1 Zigzag Cycle Detection

If there are variable nodes with erasures after BP decoding, the proposed decoder searches the zigzag cycles with BP decoding erasures. In other words, the proposed decoder removes the stopping sets except the zigzag cycles from the residual graph after BP decoding.

A residual graph after BP decoding is divided into some connected subgraphs. From Definition 1, a connected graph in a residual graph is not zigzag cycle if the connected subgraph contains the node of degree more than two in the residual graph. Hence, if we remove such connected subgraphs, we are able to detect the zigzag cycles with decoding erasures.

The detection of zigzag cycles is detailed in Algorithm 1. In this algorithm, there are three messages “0”, “1” and “−1”. The variable nodes sending the message “0” are successfully decoded under BP decoding. The variable nodes sending the message “−1” are not in zigzag cycles with BP decoding erasures. If variable nodes can be in zigzag cycles with BP decoding erasures, the variable nodes send the message “1”.

Steps 2–11 in Algorithm 1 carry out the initialization of the variable nodes. If a variable node with BP decoding erasure is of degree more than two, the connected subgraph which contains the variable node is not zigzag cycle. Hence such variable node sends the message “−1”. If a variable node with BP decoding erasure is of degree two, the connected subgraph which contains the variable node can be a zigzag cycle. Hence such variable node sends the message “1”.

Steps 12–16 in Algorithm 1 carry out the initialization of the check nodes. If a check node receiving the message “−1” or receiving more than two messages “1”, the check node sends the message “−1” since the connected subgraph which contains the check node is not zigzag cycle.

Steps 17–29 are the iteration step of Algorithm 1. If a node receives the message “−1”, the node sends the message “−1” since the connected subgraph which contains the check node is not zigzag cycle. Which contains the variable node is not zigzag cycle. Hence such variable node sends the message “1”. If a variable node receiving the message “1”, the variable node sends the message “1”.

4.2 MP Decoding Algorithm on Zigzag Cycles

In the previous section, we get the zigzag cycles in the residual graph. In this section, we realize MAP decoding on zigzag cycles by an MP algorithm for the BEC. In other words, we propose an MP algorithm which gives A

Input: The set D of indices of the variable node with BP decoding erasures
Output: The set A of indices of the variable node in the zigzag cycles with BP decoding erasures

---

Algorithm 1 Zigzag cycle detection

Input: The set $D$ of indices of the variable node with BP decoding erasures
Output: The set $A$ of indices of the variable node in the zigzag cycles with BP decoding erasures

1. $\ell \leftarrow 0$, $A^{(0)} \leftarrow D$
2. for $i \in D$ do
   3. if the degree of the $i$-th variable node is more than two then
   4. the $i$-th variable node sends “−1”, $A^{(i)} \leftarrow A^{(i)} \setminus \{i\}$
   5. else
   6. the $i$-th variable node sends “1”
   7. end if
9. for $i \in [1; N] \setminus D$ do
10. the $i$-th variable node sends “0”
11. end for
12. for $j \in [1; M]$ do
13. if the $j$-th check node receives “−1” or more than two “1” then
14. the $j$-th check node sends “−1”
15. end if
16. end for
17. repeat
18. $\ell \leftarrow \ell + 1$, $A^{(\ell)} \leftarrow A^{(\ell-1)}$
19. for $i \in A^{(\ell)}$ do
20. if the $i$-th variable node receives “−1” then
21. the $i$-th variable node sends “−1”, $A^{(i)} \leftarrow A^{(i)} \setminus \{i\}$
22. end if
23. end for
24. for $j \in [1; M]$ do
25. if the $j$-th check node receives “−1” then
26. the $j$-th check node sends “−1”
27. end if
28. end for
29. until $A^{(\ell)} = A^{(\ell-1)}$
30. $A \leftarrow A^{(\ell)}$ and outputs $A$.
Algorithm 2 Decoding algorithm on zigzag cycles

**Input:** The set $\mathcal{A}$ of indices of the variable nodes in the zigzag cycle with BP decoding erasures and syndrome $s$

**Output:** The decoding result $\{\hat{x}_i\}_{i=1}^n$

1. for $i \in \mathcal{A}$ do
   2. $(\phi_{i,j}^{(0)}, p_{i,j}^{(0)}) \leftarrow (0, \hat{0}) \forall j \in N_i(i)$
   3. end for
4. $\ell \leftarrow 1$
5. while $\mathcal{A} \neq 0$ do
   6. for $i \in N_\mathcal{A}(\mathcal{A})$ do

of Eqs. (4), (5), namely 0. The second component $p_{i,j}^{(0)}$ of the initial message represents the index of the variable node which sends the initial message.

Steps 6–11 in Algorithm 2 execute the check node calculation at the $\ell$-th iteration. Let $N_\mathcal{A}(\mathcal{A})$ be the set of the indices of the check nodes adjacent to the variable nodes in $\mathcal{A}$, i.e., $N_\mathcal{A}(\mathcal{A}) := \cup_{j \in \mathcal{A}}N_i(i)$. Note that the calculation of $\phi_{i,j}^{(f)}$ is carried out as the recurrence Eqs. (4), (5).

Steps 12–25 in Algorithm 2 execute the variable node calculation at the $\ell$-th iteration. If $\phi_{i,j}^{(f)} = 0$ for $j \in N_i(i)$, the first components of the incoming messages $\phi_{i,j}^{(f)}, \phi_{j,i}^{(f)}$ to the $i$-th variable node give $A_{\mathcal{X}_i}$ and $B_{2,\mathcal{X}_i}$. If the condition of Step 18 is true, i.e., the submatrix corresponding to the zigzag cycle is non-singular, the MAP decoding result is given as Step 19. Recall that there are no zigzag cycles of weight in $[1, w]$ with $\beta \neq 1$. If Step 20 is true, i.e., $\beta \neq 1$ and $\phi_{i,j}^{(f)} = 0$, then we set $\hat{x}_i = 0$. Otherwise, MAP decoding has failed since the submatrix corresponding to the zigzag cycle is singular. Hence, in Step 23, set the decoding result $\hat{x}_i$ as $0$ and remove the $i$-th variable node from the set of indices of the variable nodes in $\mathcal{A}$. If $\mathcal{A} = 0$, then the algorithm stops.

**Remark 1:** Consider a zigzag cycle of weight $w$ labeled with $h_1, h_1, \ldots, h_{\ell}, h_{\ell}, h_{\ell}, h_{\ell}$, where $\ell$ is the first components of the messages in Algorithm 2 satisfy for $i, \ell \in [1; w]$

$$a_i^{(f)} = \phi_{i,-\ell}^{(f)} = \psi_{-\ell,-\ell}^{(f-1)}, \quad b_i^{(f)} = \phi_{i,-\ell+1}^{(f)} = \psi_{-\ell+1,-\ell}^{(f-1)}.$$
GTEP is $O(m|D|^2 + N)$ to carry out the Gaussian eliminations and to store the indices of variable nodes in residual graph. On the other hand, the time and space complexity of the proposed algorithm is upper bounded by $O(|D|^2)$ and $O((m + [\log_2 N])|D| + N)$, respectively.

5. MP Decoder with Decoding on Zigzag Cycles for MBIOS Channel

In this section, we extend the decoding algorithm proposed in the previous section to the MBIOS channels. If we are able to detect the symbols with decoding failures for the MBIOS channels, the decoding algorithm proposed in the previous section is easily extended to the MBIOS channels. Hence, firstly, this section proposes a method to detect the symbols with decoding failures for the MBIOS channels. Secondly, we extend the decoding algorithm proposed in the previous section to the MBIOS channels.

5.1 Detection of the Symbols with Decoding Failures

To detect the symbols with decoding failures for the irregular non-binary LDPC codes over the MBIOS channels, we define the stationarity of decoding result.

Definition 2: The $i$-th decoding result is stationary if there exist $y \in \mathbb{F}_2$, and $L$ such that $D_i^{(\ell)} = \{y\}$ for all $\ell > L$.

Note that the $i$-th symbol is eventually correct [13] if there exists $L$ such that $D_i^{(\ell)} = \{x_i\}$ for all $\ell > L$, where $x_i$ is the $i$-th transmitted symbol. Hence, if the $i$-th symbol is eventually correct, the $i$-th decoding result is stationary. Hence, we get the following fact.

Fact 1: If the $i$-th decoding result is not stationary, then the $i$-th symbol is not eventually correct.

Note that there is a possibility that the $i$-th symbol is not eventually correct if the $i$-th decoding result is stationary. However, in the case for the zigzag cycles, the $i$-th symbol is eventually correct if the $i$-th decoding result is stationary. To prove the above, we consider zigzag cycle codes. A code is a zigzag cycle code if the Tanner graph is represented by a single zigzag cycle. The proof of the following theorem is given in Appendix.

Theorem 1: We assume a zigzag cycle code of symbol code length $w$ such that the corresponding matrix is non-singular. If the $i$-th decoding result is stationary, then the $i$-th decoding result is eventually correct.

From Fact 1 and Theorem 1, the following algorithm correctly detects the set of indices $\mathcal{D}$ of symbols with decoding errors for zigzag cycles in Tanner graphs.

1. If the decoding results $(D_i^{(\ell)})_{i=1}^N$, satisfy the parity check constraints in Step 3 of the BP decoding algorithm, set $\mathcal{D} = \emptyset$.
2. If the decoding round $\ell$ reaches the maximum number of iterations $L_{\text{max}}$ in Step 3 of the BP decoding algorithm, determine $\mathcal{D}$ from the decoding results $(D_i^{(\ell)})_{i=1}^N$, $(D_i^{(\ell-1)})_{i=1}^N$, ..., $(D_i^{(2)})_{i=1}^N$ as follows:

$$\mathcal{D} = \{i \in [1; N] | \exists j \in [1; s] \text{ s.t. } D_i^{(\ell)} \neq D_j^{(\ell-1)}\}.$$

Thus, the detection of symbols with BP decoding errors is realized by storing the decoding results $(D_i^{(\ell)})_{i=1}^N$, $(D_i^{(\ell-1)})_{i=1}^N$, ..., $(D_i^{(2)})_{i=1}^N$. We refer to the parameter $s$ as the storing size. Note that there are cases where the proposed error detection algorithm does not detect symbols with BP decoding errors if the symbols with decoding errors do not form a zigzag cycle.

5.2 Symbol-Wise Peeling Algorithm

A trapping set $T$ [13] is a set of variable nodes which are not eventually correct. For the BEC case, a trapping set forms a stopping set. For the MBIOS channel case, it is known that there exist neighbors of $T$ adjacent to $T$ only once.

Hence, we see that there exist neighbors of $\mathcal{D}$ adjacent to $\mathcal{D}$ only once. We denote the set of indices of the check nodes adjacent to $\mathcal{D}$ only once, by $C_1(\mathcal{D})$. Since we regard the variable nodes in $[1; N] \setminus \mathcal{D}$ as correct, we are able to decode the symbols in the variable nodes adjacent to the check node in $C_1(\mathcal{D})$.

To decode such variable nodes, we employ the symbol-wise peeling decoder. The symbol-wise peeling decoder for the non-binary LDPC codes is a straightforward extension of the peeling decoder [9] for the binary LDPC codes. The symbol-wise peeling decoding algorithm with inputs $\mathcal{D}$ and $(\hat{x}_i^{\text{BP}})_{i=1}^N$ is described in the following:

1. Set $\hat{x}_i^{\text{PA}} \leftarrow \hat{x}_i^{\text{BP}}$ and $\hat{D}^{\text{PA}} \leftarrow \hat{D}$.
2. If $C_1(\hat{D}^{\text{PA}}) = \emptyset$, the decoder terminates and outputs $(\hat{x}_i^{\text{PA}})_{i=1}^N$ and $\hat{D}^{\text{PA}}$.
3. Choose an index $j$ of a check node from $C_1(\hat{D}^{\text{PA}})$ uniformly. Let $i$ be the unique element in $\hat{D}^{\text{PA}} \cap N_\ell(j)$. Set $\hat{x}_i^{\text{PA}} \leftarrow h_{ij}^{-1} \sum_{e \in N_\ell(j)} h_{ij} \hat{x}_e^{\text{PA}}$, and $\hat{D}^{\text{PA}} \leftarrow \hat{D}^{\text{PA}} \setminus \{i\}$.
4. Go to Step 2.

Since this algorithm is a straightforward extension of the binary peeling decoder, the algorithm is realized by an MP algorithm.

5.3 Decoding Algorithm for MBIOS Channels

In this section, we propose an MP decoding algorithm with decoding on zigzag cycles for the MBIOS channels. The MP decoding algorithm with decoding on zigzag cycles is divided into the following 4 steps:

1. BP decoder (Sect. 2.3) with error detection (Sect. 5.1),
2. symbol-wise peeling algorithm (Sect. 5.2),
3. zigzag cycle detection (Sect. 4.1),
4. decoding on zigzag cycles (Sect. 4.2).

Figure 4 illustrates the data flow of the MP decoder with decoding on zigzag cycles for the MBIOS channels.
The BP decoder with error detection gives the set $\hat{e}$ of indices of variable nodes with BP decoding errors and BP decoding outputs $\hat{x}^{BP}$. By using $\hat{e}$ and $\hat{x}^{BP}$, the symbol-wise peeling algorithm decides the set $\hat{D}^{PA}$ of indices of variable nodes with decoding errors and the decoding outputs $\hat{x}^{PA}$. The zigzag cycle detection determines the set $\mathcal{A}$ of indices of variable nodes in the zigzag cycles with decoding errors from $\hat{D}^{PA}$. The syndrome calculation derives the syndrome $\hat{s}$ from $\hat{x}^{PA}$. From $\mathcal{A}$ and syndrome $s$, the decoding algorithm on zigzag cycles gives the decoding output $\hat{x}$ of proposed decoder.

5.4 Decoding Complexity

For the error detection, the proposed decoding algorithm requires $msN$ memories and $(s-1)N$ equality testing. The symbol-wise peeling algorithm needs $mN$ + $n$ memories to express $\hat{x}^{PA}_{x_i}$ and $\hat{D}^{PA}$. Moreover, in Step 3, the symbol-wise peeling algorithm executes deg($c_j$) finite field multiplications and deg($c_j$) – 2 finite field addition, where deg($c_j$) is the degree of the check node $c_j$. Since the number of iterations of the symbol-wise peeling algorithm is upper bounded by $|\hat{D}|$, in total, the symbol-wise peeling algorithm execute at most $|\hat{D}|$Deg($P(x)$) finite field multiplications, where Deg($P(x)$) is the degree of the polynomial $P(x)$, i.e., the maximum degree of the check nodes.

6. Simulation Result

This section compares the symbol error rates in the error floors for non-binary LDPC codes over the BECs and the BAWGN channels by the BP decoding algorithm with by the proposed decoding algorithm. In this section, as a regular LDPC code, we employ the (2,4)-regular non-binary LDPC codes over $\mathbb{F}_2^s$ with code length 168 as an example of irregular LDPC codes, we employ the irregular non-binary LDPC codes with the degree distribution pair $\Lambda(x) = 195x^3 + 26x^5 + 29x^4 + 2x^3$, $P(x) = 36x^4 + 90x^5$ over $\mathbb{F}_2^8$.

Figures 5(a) and 5(b) demonstrate the symbol erasure rates for the regular and irregular non-binary LDPC codes over the BEC, respectively. The red curves and the green curves give the symbol erasure rates by the BP algorithm and the proposed decoding algorithm, respectively. The dashed lines and the solid lines give the symbol erasure rates for the non-binary LDPC codes constructed in the cycle cancellation [5] and the improved cycle cancellation [11], respectively. From Figs. 5(a) and 5(b), we see that the proposed decoding algorithm improves the decoding erasure rates in the error floor. Moreover, we see that the non-binary LDPC codes constructed in the improved cycle cancellation outperform those constructed in the cycle cancellation for the proposed decoding algorithm.

Figure 6(a) (resp. Fig. 6(b)) compares the symbol erasure rates for the regular (resp. irregular) non-binary LDPC codes constructed by the algorithm proposed in [6] over the BAWGN channels under the BP algorithm and the proposed decoding algorithm with the storing size $s = 1, 2, 3$. From Figs. 6(a) and 6(b), we see that the proposed decoding algorithm improves the decoding error rates in the error floors. In those cases, there are not much difference in the symbol error rates among $s \in [2; 10]$. 7. Conclusion

In this paper, we have proposed a decoding algorithm which lower decoding error rates in the error floors for non-binary LDPC codes over the MBIOS channel. We have shown that the proposed decoding algorithm is realized by means of an MP algorithm.

References

Without loss of generality, we assume the zigzag cycle code of weight $w$ labeled with $h_1, h_2, \ldots, h_w$, as described in Fig. 1. We assume that the all-zero codewords are sent without loss of generality for analyzing the decoding error rate [14]. Since the matrix corresponding to the zigzag cycle code is non-singular, the parameter $\beta$, defined in Eq. (1), is not equal to 1. Let the order of $\beta$ be denoted by $\sigma$. Note that $\sigma > 1$ since $\beta \neq 1$.

Let $\bar{\Psi}_v^{(t)}$ be the unnormalized message from the $v$-th variable node to the $i$-th check node at the $t$-th iteration. For all $x \in \mathbb{F}_2^w$, $t \geq 1$ and $i \in [1; w]$, the unnormalized message in the zigzag cycle code of weight $w$ is written as follows:

\[
\bar{\Psi}_v^{(0)}(x) := C_i(x), \quad \bar{\Psi}_v^{(t)}(x) := C_i(x)\bar{\Psi}_v^{(t-1)}(\gamma_{i-1}^{-1}x),
\]

where $\gamma_i := h_{i-1}^{-1}h_{i+1}$, $\gamma_0 = \gamma_w$, and $\bar{\Psi}_v^{(t)}(\gamma_{i-1}x) = \bar{\Psi}_v^{(t)}(x)$ for $i, j \in [1, w]$. These notations give $D_i^{(t)} = \text{argmax}_{x \in \mathbb{F}_2^w} \bar{D}_i^{(t)}(x)$.

In the same way to the proof of Theorem 1 in [6], we have for all $t \geq 1$, $x \in \mathbb{F}_2^w$ and $i \in [1; w]$

\[
\bar{D}_i^{(t)}(x) = \{B(X; x)^2\bar{C}_i(x),
\]

where $\chi_i = \prod_{j=1}^{w-1} \gamma_j$ and $B(x) := \prod_{j=1}^{w-1} \prod_{k=1}^{\gamma_j} C_k(\beta^j x \prod_{j'=0}^{w} \gamma_{j'})$. Note that $B(x) = B(\beta x)$ for all $x \in \mathbb{F}_2^w$. From these equations, we have for all $t \geq 1$, $x \in \mathbb{F}_2^w$ and $i \in [1; w]$

\[
\bar{D}_i^{(t)}(x)\bar{D}_i^{(t-1)}(x) = \{B(X; x)^{4t} = (B(\beta x))^{4t} = \bar{D}_i^{(t)}(x)\bar{D}_i^{(t-1)}(x)\}.
\]

We will show that the $i$-th symbol is eventually correct if the $i$-th decoding result is stationary. Recall that the $i$-th

decoding result is stationary if there exist $L$ and $x \in \mathbb{F}_{2^n}$ such that $D_i^\ell(x) > D_i^\ell(y)$ for all $\ell > L$ and $y \in \mathbb{F}_{2^n} \setminus \{x\}$. From Eq. (A-1), for all $t \geq 1$, if $D[\text{iter}]^{\text{iter}}(x) > D[\text{iter}]^{\text{iter}}(y)$ for all $y \in \mathbb{F}_{2^n} \setminus \{x\}$, namely $D[\text{iter}]^{\text{iter}}(x) > D[\text{iter}]^{\text{iter}}(\beta x)$, then $D_i^{\text{iter}-1}(\beta x) > D_i^{\text{iter}-1}(x)$. Hence, the $i$-th decoding result is not stationary if the $i$-th symbol is not correct. □
